[PLT-8861: Document Discovery+Assistant process in Confluence](#) DONE

- *Watsonx Discovery* is a data repository with added intelligence - it supports extracting relevant passages from the uploaded document(10-K in this case) and passes the **top n**(here n=2, can be configured) passages to the LLM. These extracted passages however are not very human readable - therefore the LLM, using a model(here, LAMA) - **enriches** the summarized text to be more **human readable** and returns a concise response.
- The Assistant is simply the UI that is responsible for sending the query to the backend and retrieving/displaying the response
- In the Manage Collections Tab, there are currently 2 datasets - The ESG 10K dataset is the repository of uploaded 10K files(treated as one of the *inputs apart from the user query to assistant*), and the ESG Mapping Dataset which is where the outputs are stored
 - New 10Ks are uploaded to Discovery by clicking on a collection, and then on *Upload Data*. The upload process can take between **5-10** minutes.
 - Once complete, the *Try it out* button will take you to *Document Retrieval* where you can type for instance "*What are the environmental and social topics that coke covers in its 10K filings?*"
 - The *View Passage in Document* button allows verifying that the extracted passage(s) are indeed sourced from the 10K of the company in question

Process of Preliminary Testing of Prompts:

Assuming company X does not already have its 10K uploaded in Discovery:

1. Ask assistant the standard question "*What are the environmental and social topics that X cover in its 10K filings?*"
2. Note quality of response - most likely will be irrelevant since 10K not uploaded yet
3. Upload the 10K to discovery
4. Ask the same question again
5. Note improved response with better citation("How do we know" dropdown)
